The Network Data Sanitization Problem

- Anonymize a packet trace or flow log s.t.:
 1. Researchers gain maximum utility
 2. Adversaries w/ auxiliary information do not learn sensitive information

Methods of Sanitization

- Pseudonyms for IPs
 - Strict prefix-preserving [FXAM04]
 - Partial prefix-preserving [PAPL06]
 - Transaction-specific [OBA05]
- Other data fields anonymized in **reaction** to attacks
 - e.g., time stamps are quantized due to clock skew attack [KBC05]

Notable Attacks

- Several active and passive attacks exist...
 - Active probing [BA05, BAO05, KAA06]
 - Host profiling [CWCMR07, RCMT08]
 - Identifying web pages [KAA06, CCWMMR07]

The Underlying Problem

- Attacks can be generalized as follows:
 1. Identifying information is encoded in the anonymized data
 - Host behaviors for profiling attacks
 2. Adversary has external information on true identities
 - Public information on services offered by a host
 3. Adversary maps true identities to pseudonyms

Our Goals

1. Find objects at risk of deanonymization
 2. Compare anonymization systems and policies
 3. Model hypothetical attack scenarios
- *Focus on 'natural' sources of information leakage*

Outline

- Adversarial Model
- Defining Objects
- Auxiliary Information
- Calculating Anonymity
- Evaluation

Adversarial Model

- Adversary's goal: map an *anonymized object* to its *un-anonymized* counterpart

Defining Objects

- Consider network data as a database
 - n rows, m columns
 - Each row is a packet (or flow) record
 - Each column is a data field (e.g., source port)
- Fields can induce a ***probability distribution***
 - Sample space defined by values in the field
 - Represented by random variables in our analysis

Defining Objects

ID	Local IP	Local Port	Remote IP	Remote Port
1	10.0.0.1	80	192.168.2.5	1052
2	10.0.0.2	3069	10.0.1.5	80
3	10.0.0.1	80	192.168.2.10	4059
4	10.0.0.1	21	192.168.6.11	5024
...				

Defining Objects

Local IP
10.0.0.1
10.0.0.2
10.0.0.1
10.0.0.1
...

Defining Objects

- Combinations of fields can leak information even if the fields are indistinguishable in isolation
 - A real-world adversary has a directed plan of attack on a certain subset of fields
 - Our analysis must consider a much larger set of potential fields
- Use feature selection methods based on mutual information to find related fields
 - Limits computational requirements

Defining Objects

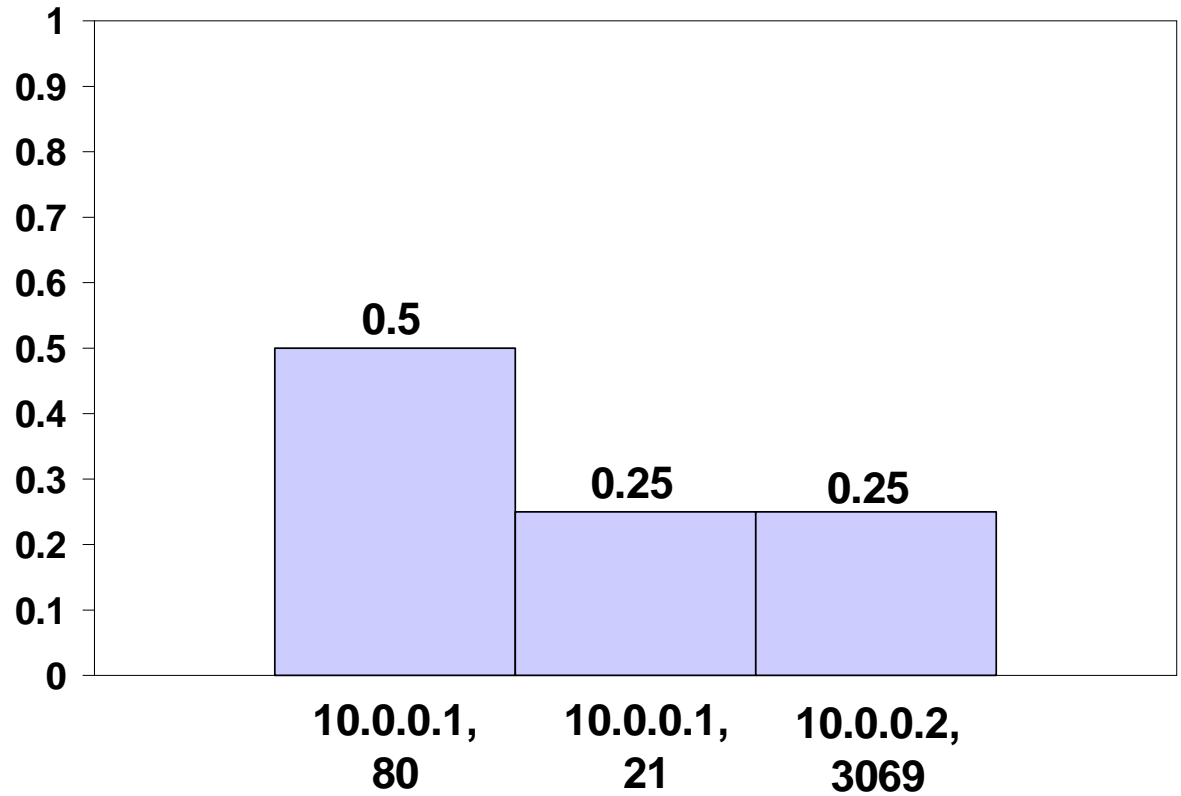

- A ***feature*** is a group of correlated fields
 - Calculate ***normalized mutual information***
 - Group into pairs if mutual information $> t$
 - Merge groups that share a field in to a feature
- A ***feature distribution*** is the joint distribution over the fields in the feature

Defining Objects

ID	Local IP	Local Port	Remote IP	Remote Port
1	10.0.0.1	80	192.168.2.5	1052
2	10.0.0.2	3069	10.0.1.5	80
3	10.0.0.1	80	192.168.2.10	4059
4	10.0.0.1	21	192.168.6.11	5024
		...		

Defining Objects

Local IP	Local Port
10.0.0.1	80
10.0.0.2	3069
10.0.0.1	80
10.0.0.1	21
...	

Defining objects

- An ***object*** is a set of feature distributions over records produced due its presence
 - e.g., host objects – feature distributions induced by records sent from or received by a given host

Defining Objects

ID	Local IP	Local Port	Remote IP	Remote Port
1	10.0.0.1	80	192.168.2.5	1052
2	10.0.0.2	3069	10.0.1.5	80
3	10.0.0.1	80	192.168.2.10	4059
4	10.0.0.1	21	192.168.6.11	5024
...				

Defining Objects

ID	Local IP	Local Port	Remote IP	Remote Port
1	10.0.0.1	80	192.168.2.5	1052
3	10.0.0.1	80	192.168.2.10	4059
4	10.0.0.1	21	192.168.6.11	5024
		...		

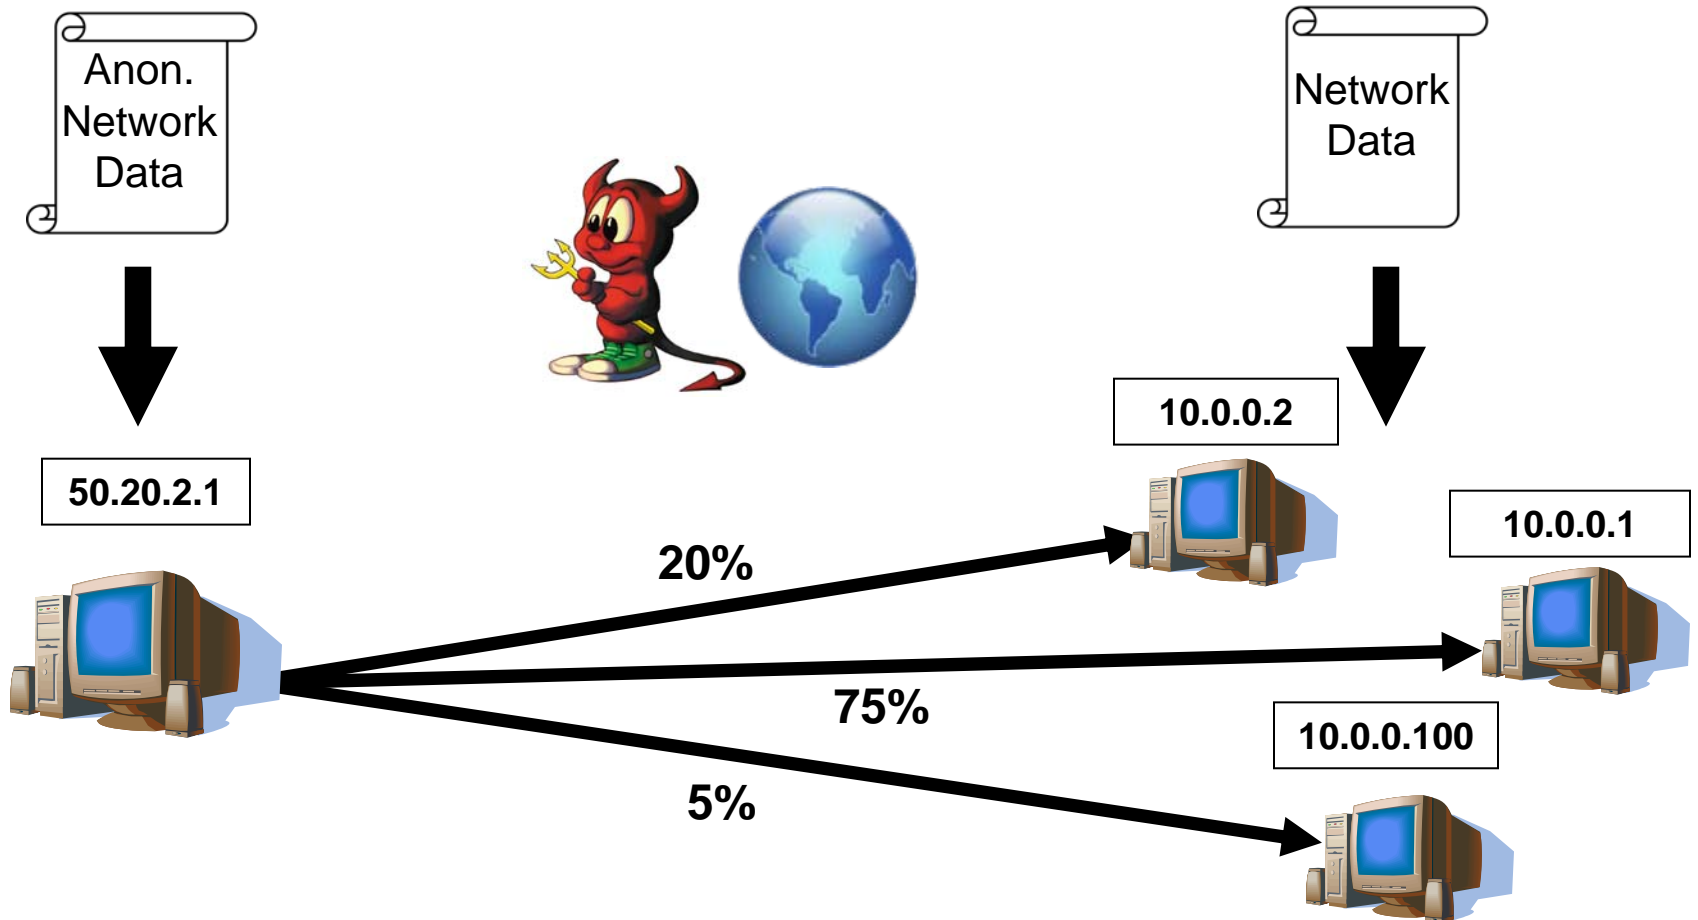

Defining Objects

ID	Local IP	Local Port	Remote IP	Remote Port
1	10.0.0.1	80	192.168.2.5	1052
3	10.0.0.1	80	192.168.2.10	4059
4	10.0.0.1	21	192.168.6.11	5024

Adversarial Model

Adversarial Model

Auxiliary Information

- ***Auxiliary information*** captures the adversary's external knowledge
 - Initially, adversary only has knowledge obtained from meta-data
 - As adversary deanonymizes objects, new knowledge is gained
- Used to iteratively refine mapping between anonymized and unanonymized objects

Auxiliary Information

Local IP:

Prefix-Preserving

Anonymized
Values

50.20.2.1
50.20.2.2
50.20.2.3
...

Unanonymized
Values

{10.0.0.1, ..., 10.0.0.255}
{10.0.0.1, ..., 10.0.0.255}
{10.0.0.1, ..., 10.0.0.255}
...

Auxiliary Information

Local IP:

Prefix-Preserving

Anonymized
Values

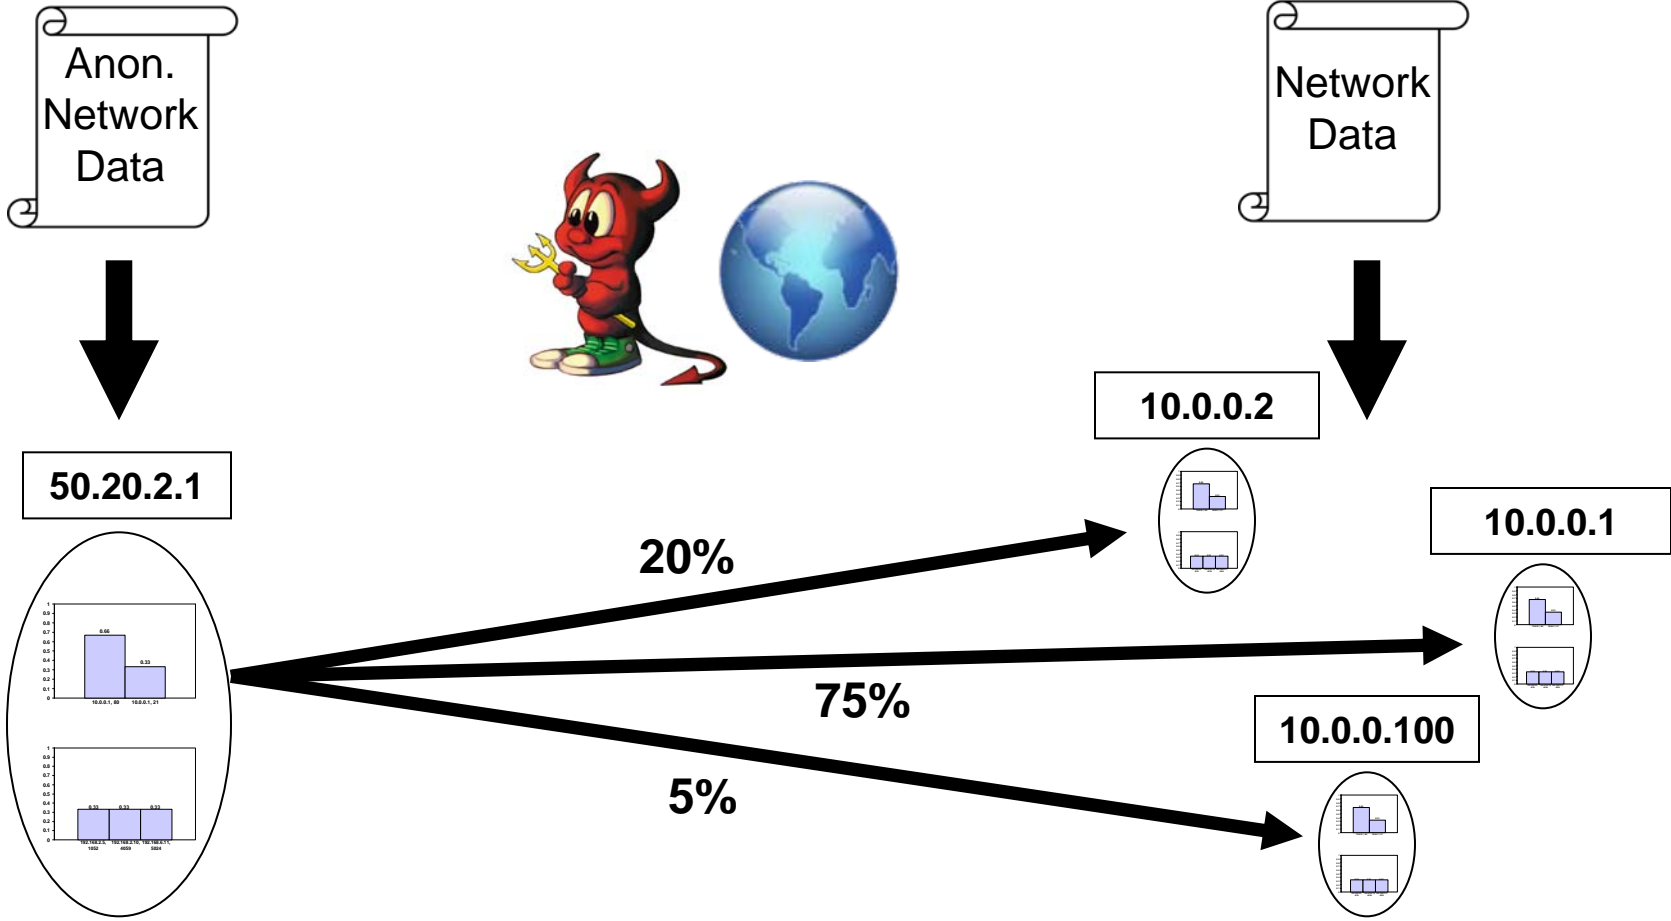

50.20.2.1
50.20.2.2
50.20.2.3
...

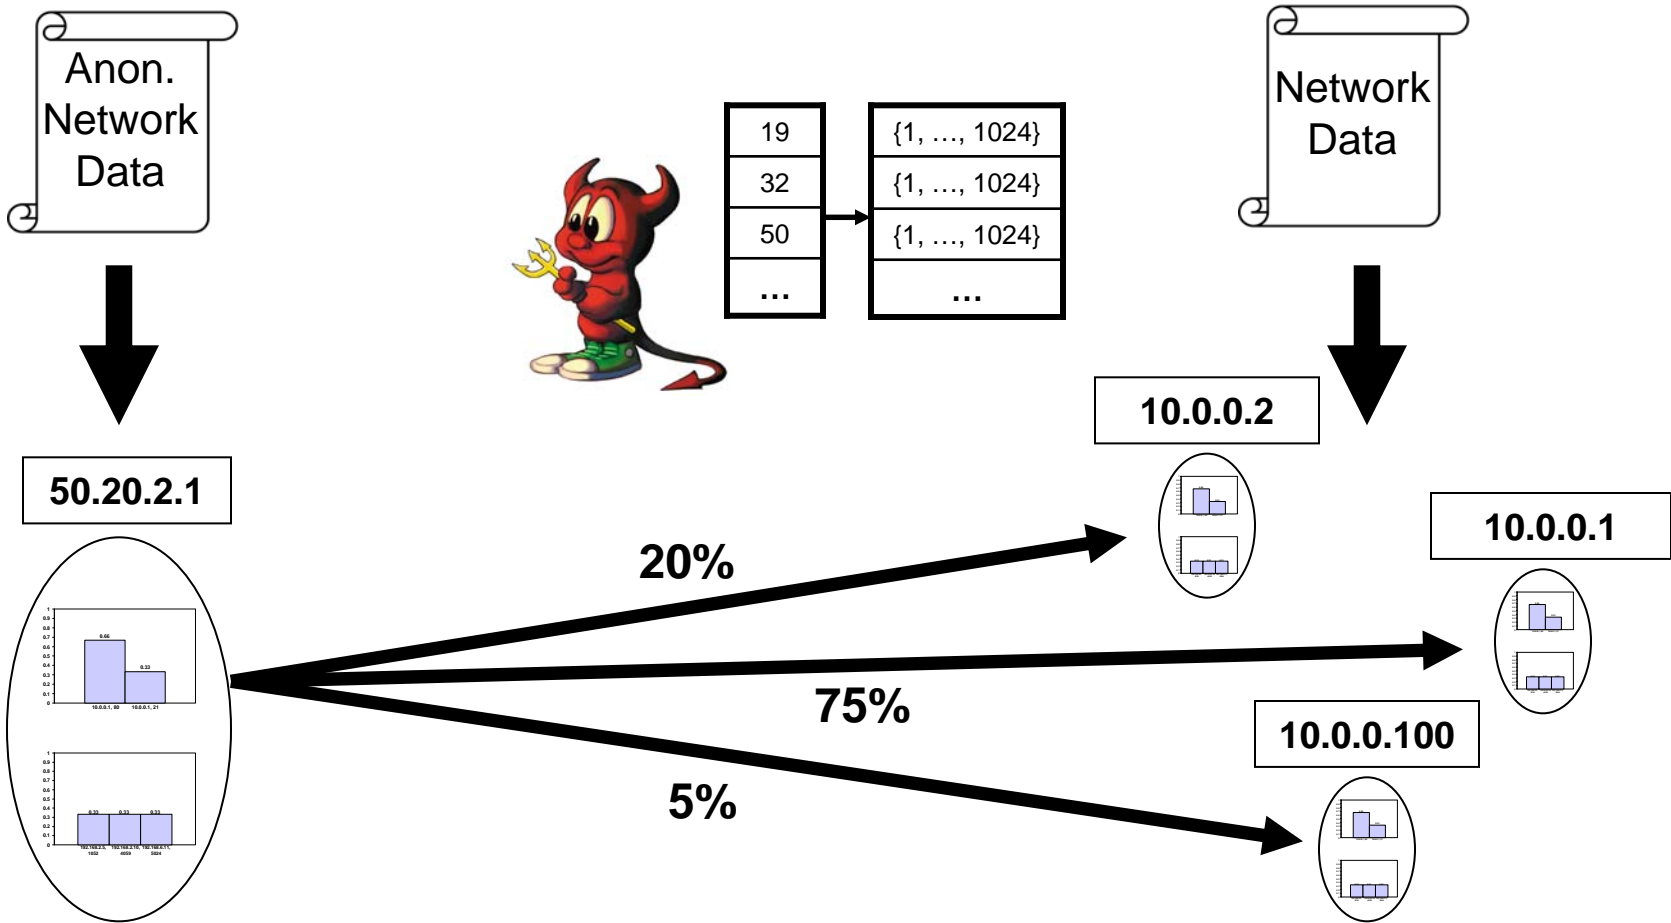

Unanonymized
Values

{10.0.0.1}
{10.0.0.2, 10.0.0.3}
{10.0.0.2, 10.0.0.3}
...

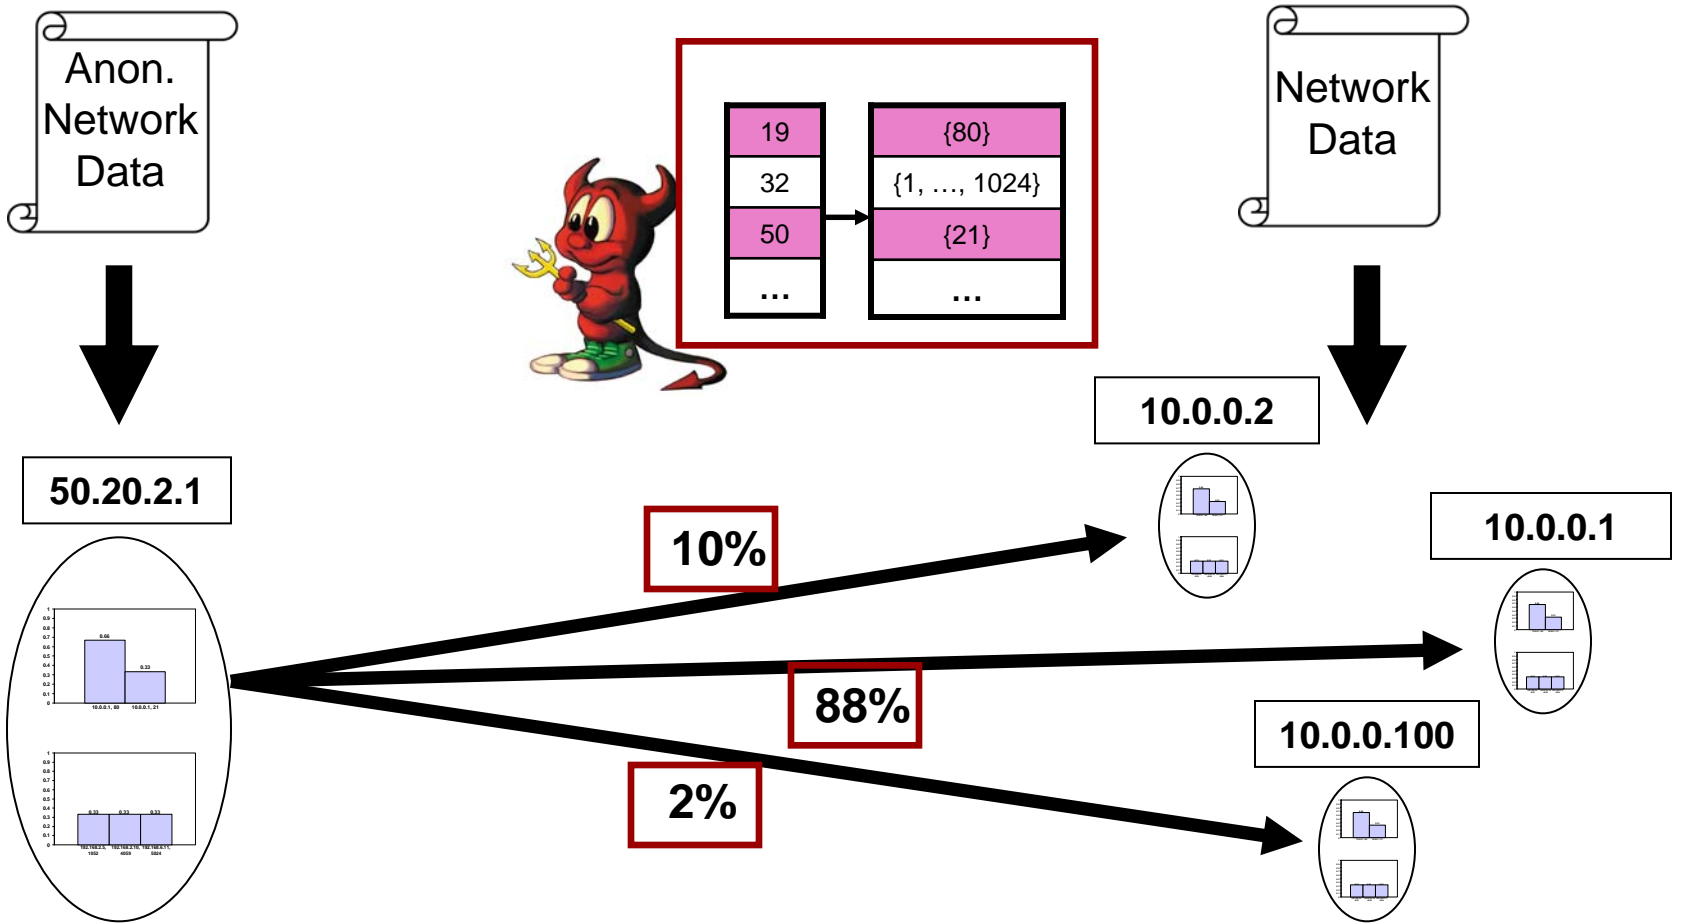

Adversarial Model

Adversarial Model

Adversarial Model

Calculating Anonymity

- Compare each feature distribution of anonymized object against all unanonymized objects
 - Use ***L1 similarity*** measure as a count to approximate a probability distribution
 - Use ***information entropy*** of the distribution as ***object anonymity*** with respect to the feature
- Auxiliary information dictates how the features are compared

Calculating Anonymity

- Sum of entropy across all features gives us the ***overall object anonymity***
 - Assuming features are independent due to mutual information correlation criterion
- Calculate ***conditional anonymity*** of an object via a greedy algorithm
 1. Choose lowest entropy object and assume it has been deanonymized
 2. Reverse anonymization to learn mappings
 3. Recalculate object anonymity with new auxiliary information

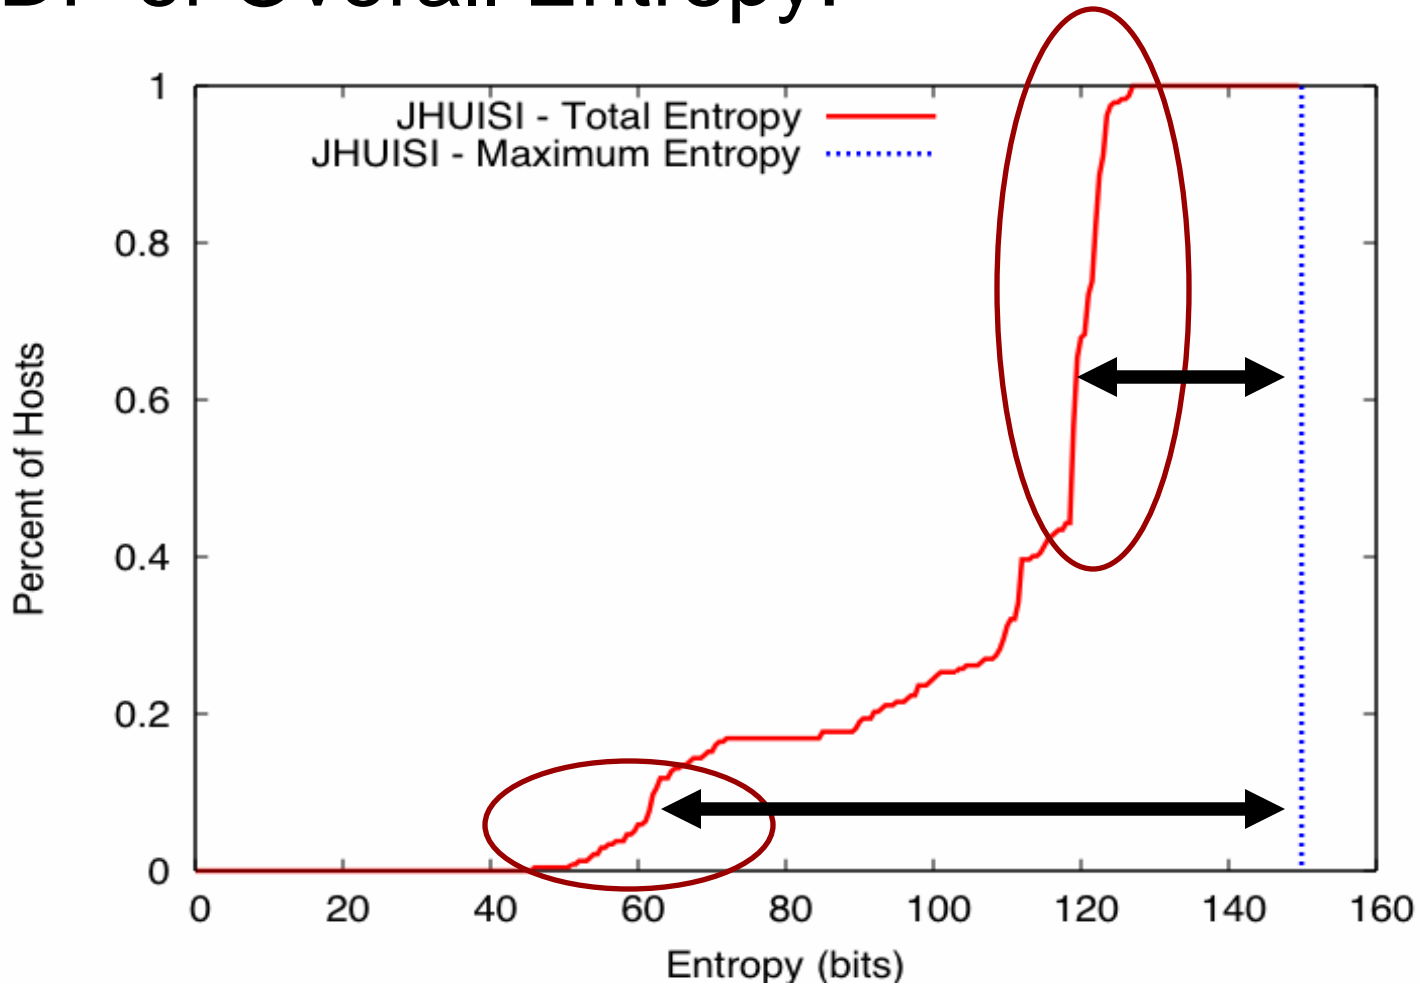

Evaluation

- Capture flow logs at the edge of the JHUISI network
 - 24 hours of data
 - 27,753 flows
 - 237 hosts on three subnets
 - Anonymized with *tcpmkpub* [PAPL06]

- Analysis of Host Objects
 - Defined by unique Local IPs
 - 19 features generated from the fields:
 - Start time, end time, local IP, local port, local size, remote IP, remote port, remote size, and protocol

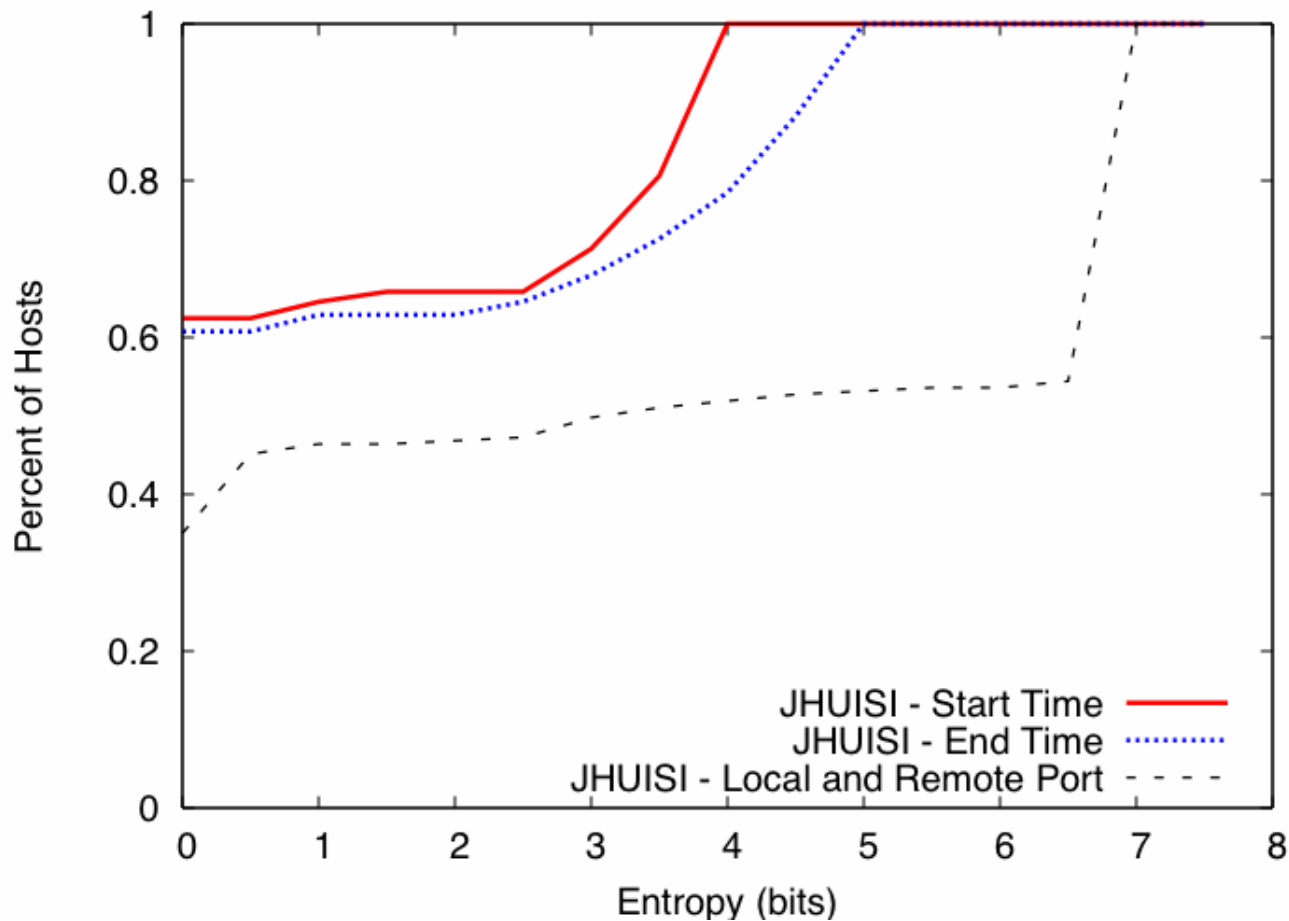

Evaluation

■ CDF of Overall Entropy:

Evaluation

■ CDF of three worst features:

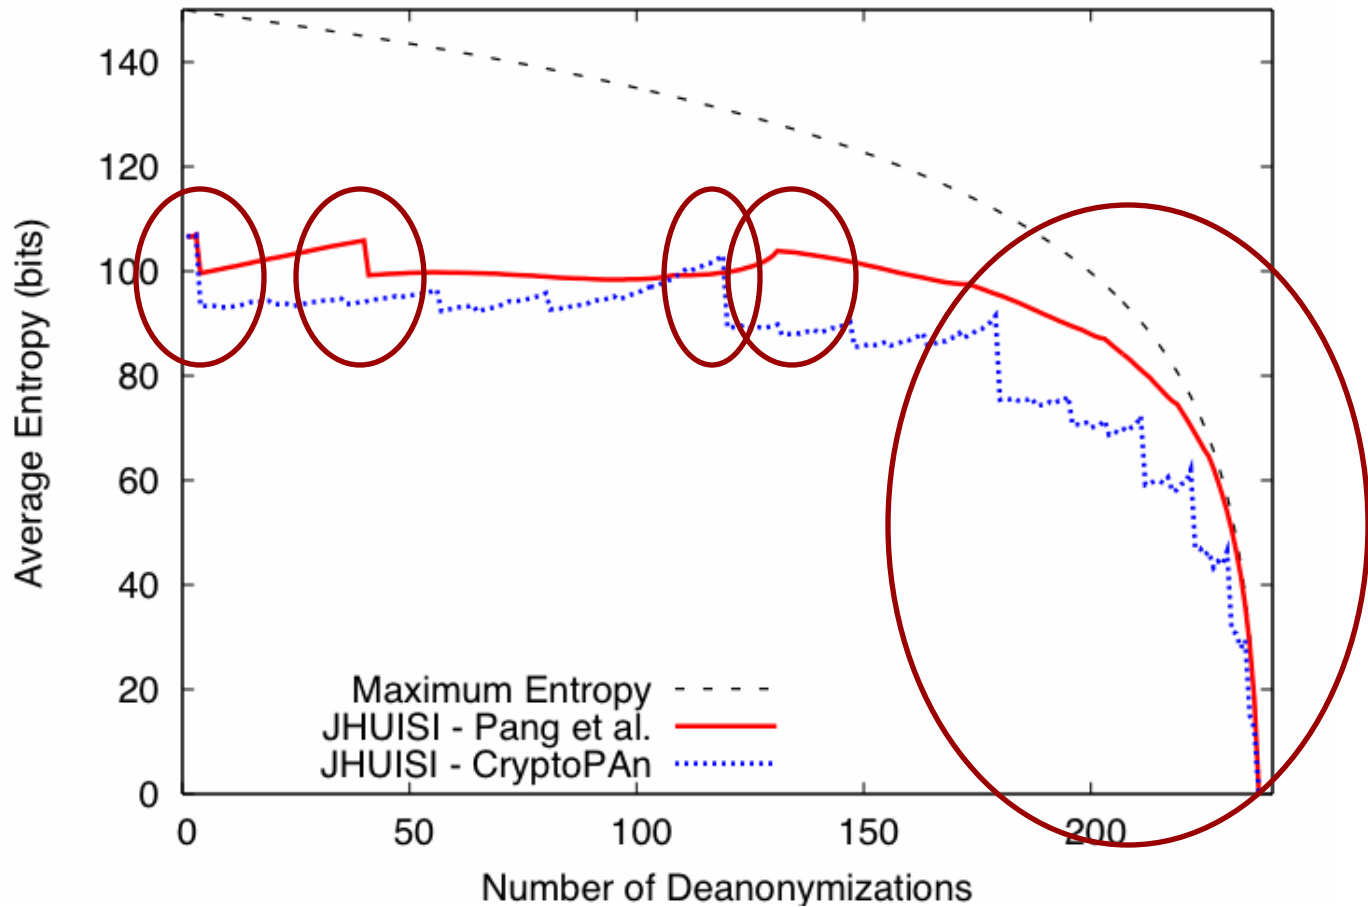

Evaluation

- Comparison of prefix-preserving schemes using conditional anonymity:
 - **CryptoPAn [FXAM04]** – if n bits of a prefix are shared in the unanonymized IP, n bits will be shared in the anonymized IP
 - **Pang *et al* [PAPL06]** – use pseudorandom permutation to anonymize host and subnet portions separately

Evaluation

■ CryptoPAn vs. Pang *et al.*:

Evaluation

- Conditional anonymity can also be used to evaluate the impact of known attacks
 - Simulate the behavioral profiling attack [CWCMR07]
 - Determine the hosts that are susceptible
 - Determine the impact of deanonymizing those hosts on those that remain

Conclusion

- Privacy risks are due to information encoded within the anonymized network data
- Provide one of the first methods for evaluating anonymized data for information leakage
 - Discover objects at risk of deanonymization
 - Compare anonymization policies and techniques
 - Simulate hypothetical attack scenarios

Calculating Anonymity

Local IP, Local Port Feature

Anonymized Object: 50.20.2.1

Unanonymized Object: 10.0.0.1

Unanon. Object	10.0.0.1
Similarity	2.0

Calculating Anonymity

Local IP, Local Port Feature

Anonymized Object: 50.20.2.1

Unanonymized Object: 10.0.0.2

Unanon. Object	10.0.0.1	10.0.0.2
Similarity	2.0	1.66

Calculating Anonymity

Local IP, Local Port Feature

Anonymized Object: 50.20.2.1

Unanonymized Object: 10.0.0.100

Unanon. Object	10.0.0.1	10.0.0.2	10.0.0.100
Similarity	32.70%	32.66%	29.51%
